# Spark

Cluster computing

J. Fernando Sánchez, Joaquín Salvachúa, Gabriel Huecas

2016

Universidad Politécnica de Madrid

## Outline i

# Background

- Higher level programming
- Avoid side effects
- Pattern matching

- A *better* Java
- Functional programming (optional)
- Actors for (coarse) concurrency

- Easy and repeatable deployment
- Lots of pre-built images @ hub.docker.com
- Building block for other tools (swarm, compose, machine...)

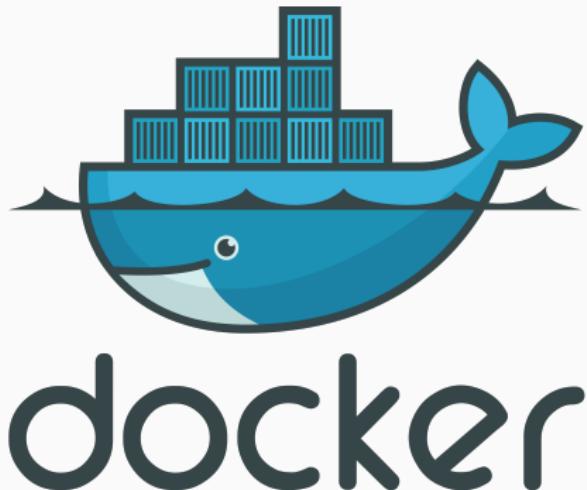

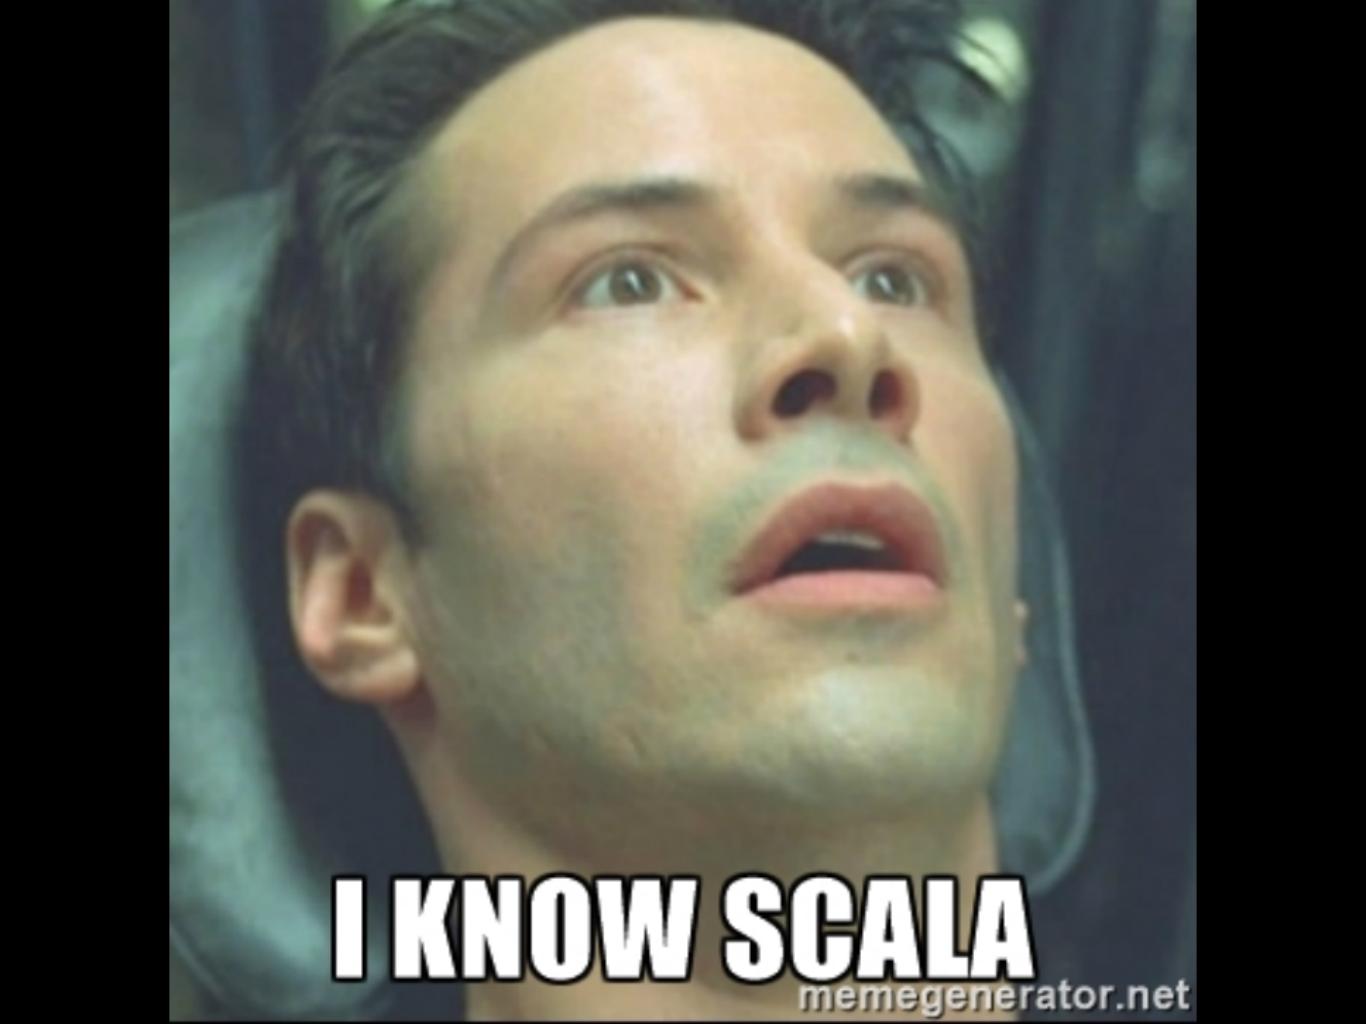

docker

I KNOW SCALA

I KNOW BIG DATA
memegenerator.net
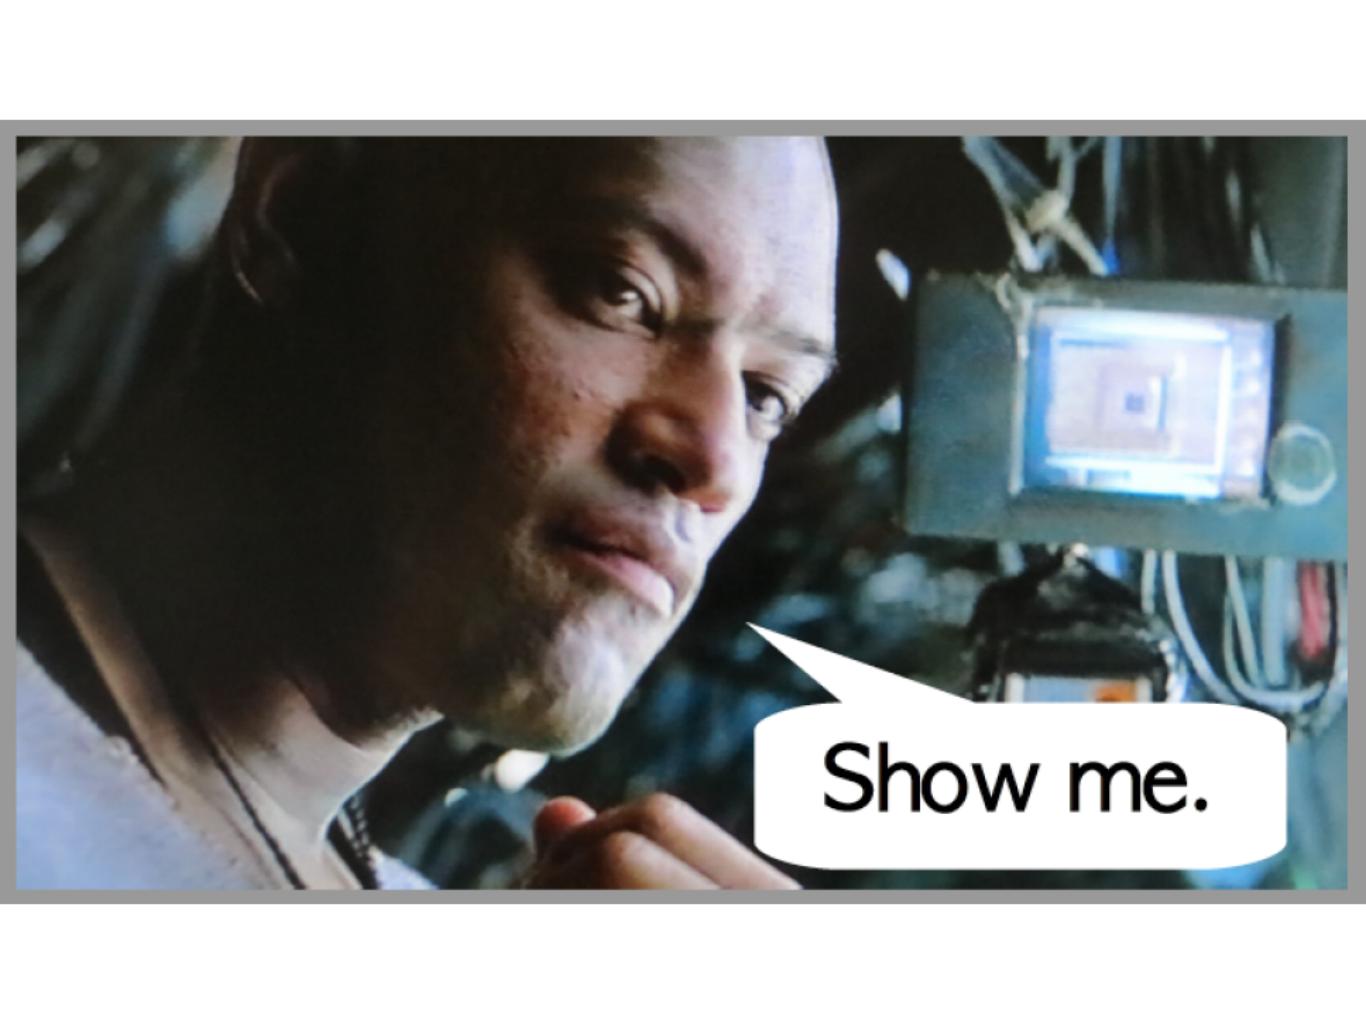

## Word count in Wikipedia

Problem: find the frequency each word is used in Wikipedia.

We have the text of all wikipedia in a text file[1]. It begins like this:

```
hi world
hi
Scala (SKAH-lah)[9] is a general-purpose
programming language. Scala has full support for
functional programming and a strong static type
system. Designed to be concise,[10] many of Scala
's design decisions were inspired by criticism of
 Java's shortcomings.[8]
```

---

[1]By happy coincidence, the first two lines are "hi world" and "hi"

## Algorithm

- Read every line
- Chunk every line into words
- Count every occurrence
- For every word, sum its occurrences

## Possible results of every step

```
(("hi world"), ("hi") ...)
List((hi, 1), (hi, 1), (world, 1) ...)
Map(hi ->(("hi", 1), (hi, 1)),
    world -> ((world, 1)) ...)
Map(hi-> 2, world -> 1 ...)
```

**Possible results of every step**

```
(("hi world"), ("hi") ...)
List((hi, 1), (hi, 1), (world, 1) ...)
Map(hi ->(("hi", 1), (hi, 1)),
    world -> ((world, 1)) ...)
Map(hi-> 2, world -> 1 ...)
```

## Possible results of every step

```
(("hi world"), ("hi") ...)
List((hi, 1), (hi, 1), (world, 1) ...)
Map(hi ->(("hi", 1), (hi, 1)),
    world -> ((world, 1)) ...)
Map(hi-> 2, world -> 1 ...)
```

## Possible results of every step

```
(("hi world"), ("hi") ...)
List((hi, 1), (hi, 1), (world, 1) ...)
Map(hi ->(("hi", 1), (hi, 1)),
    world -> ((world, 1)) ...)
Map(hi-> 2, world -> 1 ...)
```

## Running the scala shell

We will use docker.

```
docker run -it -v $PWD:Wikipedia.txt:Wiki \
           --rm williamyeh/scala
```

## Scala code

```scala
import scala.io.Source
val wiki = Source.fromFile("Wiki").getLines
wiki.flatMap(line=> line.split("␣"))
     map(x=>(x, 1)).toList
     groupBy(x => x._1)
     map({case (k, v) =>
          (k, v.foldLeft(0)((a, b) => a+b._2)))
```

## Scala code

```scala
import scala.io.Source
val wiki = Source.fromFile("Wiki").getLines
wiki.flatMap(line=> line.split(" "))
    map(x=>(x, 1)).toList
    groupBy(x => x._1)
    map({case (k, v) =>
        (k, v.foldLeft(0)((a, b) => a+b._2)))
```

```scala
import scala.io.Source
val wiki = Source.fromFile("Wiki").getLines
wiki.flatMap(line=> line.split("␣"))
     map(x=>(x, 1)).toList
     groupBy(x => x._1)
     map({case (k, v) =>
          (k, v.foldLeft(0)((a, b) => a+b._2)))
```

```scala
import scala.io.Source
val wiki = Source.fromFile("Wiki").getLines
wiki.flatMap(line=> line.split(" "))
     map(x=>(x, 1)).toList
     groupBy(x => x._1)
     map({case (k, v) =>
          (k, v.foldLeft(0)((a, b) => a+b._2)))
```

```scala
import scala.io.Source
val wiki = Source.fromFile("Wiki").getLines
wiki.flatMap(line=> line.split("␣"))
    map(x=>(x, 1)).toList
    groupBy(x => x._1)
    map({case (k, v) =>
        (k, v.foldLeft(0)((a, b) => a+b._2)))
```

Let's run it in the shell.
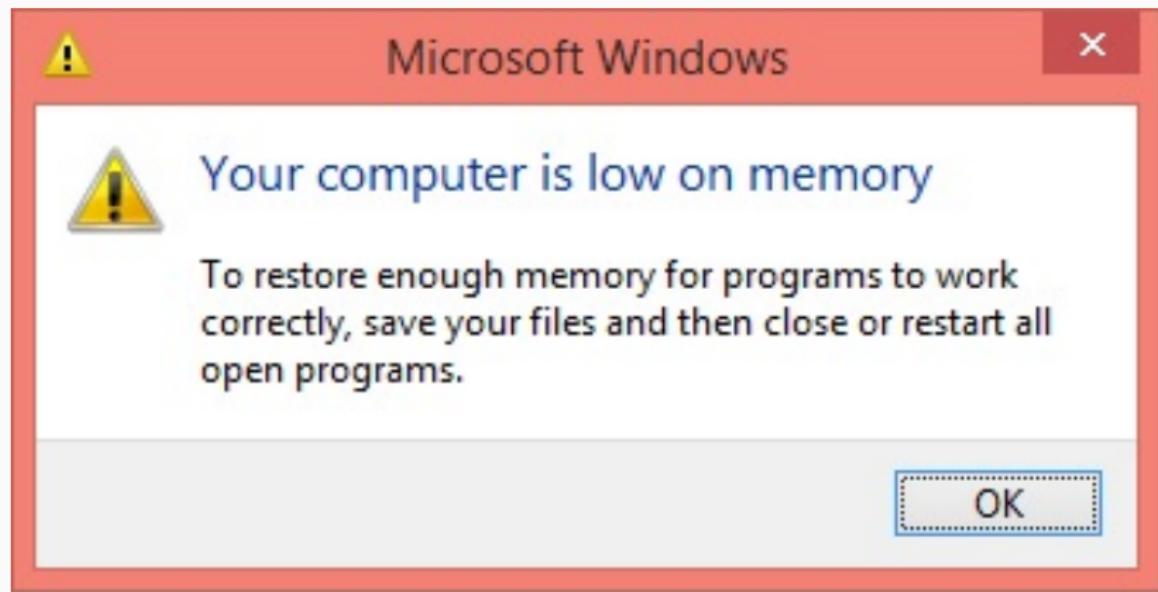

# What happened?

## Limited resources

- CPU limits our speed
    - Multi-cores help...
    - ...but real parallelism is **hard**
- RAM limits how much data you can process at the same time
    - What if you need more than 128GB?
    - You could use more than one computer...
    - ... but cluster computing is even harder than "local" parallelism
- Functional programming helps a bit

But... this was supposed to be fun, wasn't it?

# Introduction to Spark

![Apache Spark logo] *Lightning-fast cluster computing*

**Apache Spark™** is a fast and general engine for large-scale data processing.

### Latest News

Spark wins CloudSort Benchmark as the most efficient engine (Nov 15, 2016)

Spark 2.0.2 released (Nov 14, 2016)

Spark 1.6.3 released (Nov 07, 2016)

Spark 2.0.1 released (Oct 03, 2016)

Archive

## Speed

Run programs up to 100x faster than Hadoop MapReduce in memory, or 10x faster on disk.

Apache Spark has an advanced DAG execution engine that supports cyclic data flow and in-memory computing.

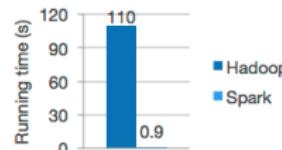

Logistic regression in Hadoop and Spark

**Built-in Libraries:**

SQL and DataFrames
Spark Streaming
MLlib (machine learning)
GraphX (graph)

Third-Party Packages

## Ease of Use

Write applications quickly in Java, Scala, Python, R.

Spark offers over 80 high-level operators that make it easy to build parallel apps. And you can use it *interactively* from the Scala, Python and R shells.

```
text_file = spark.textFile("hdfs://...")

text_file.flatMap(lambda line: line.split())
    .map(lambda word: (word, 1))
    .reduceByKey(lambda a, b: a+b)
```

Word count in Spark's Python API

# Apache Spark™ is a fast and general engine for large-scale data processing.[2]

On top of that:

- Open source (Top-level Apache project)
- Plays well with other tools

---

[2]http://spark.apache.org
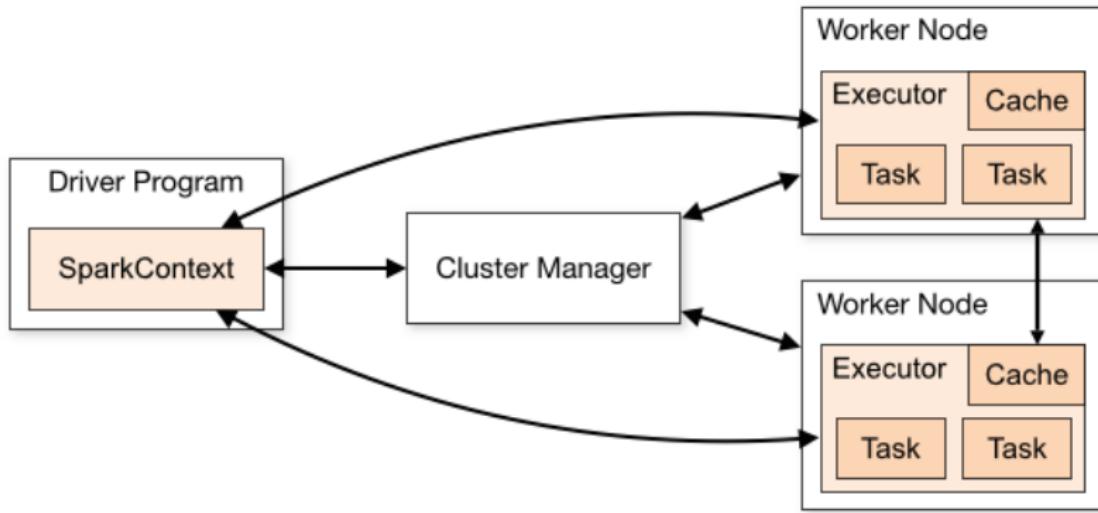

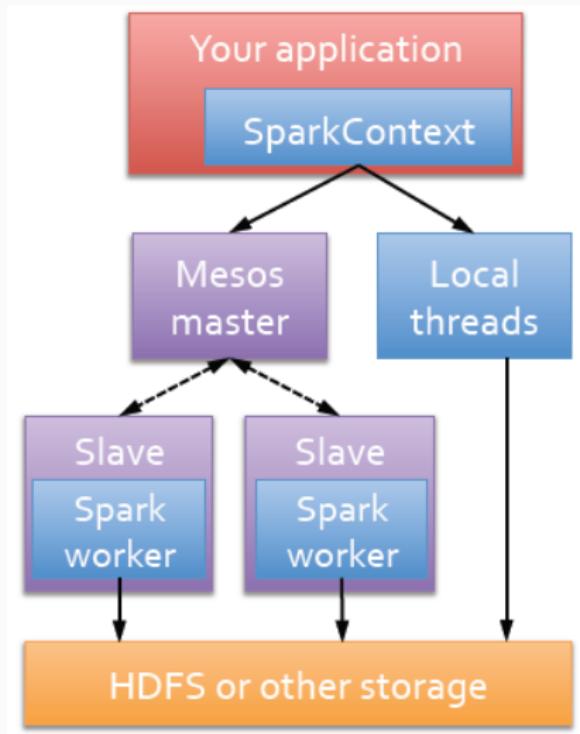

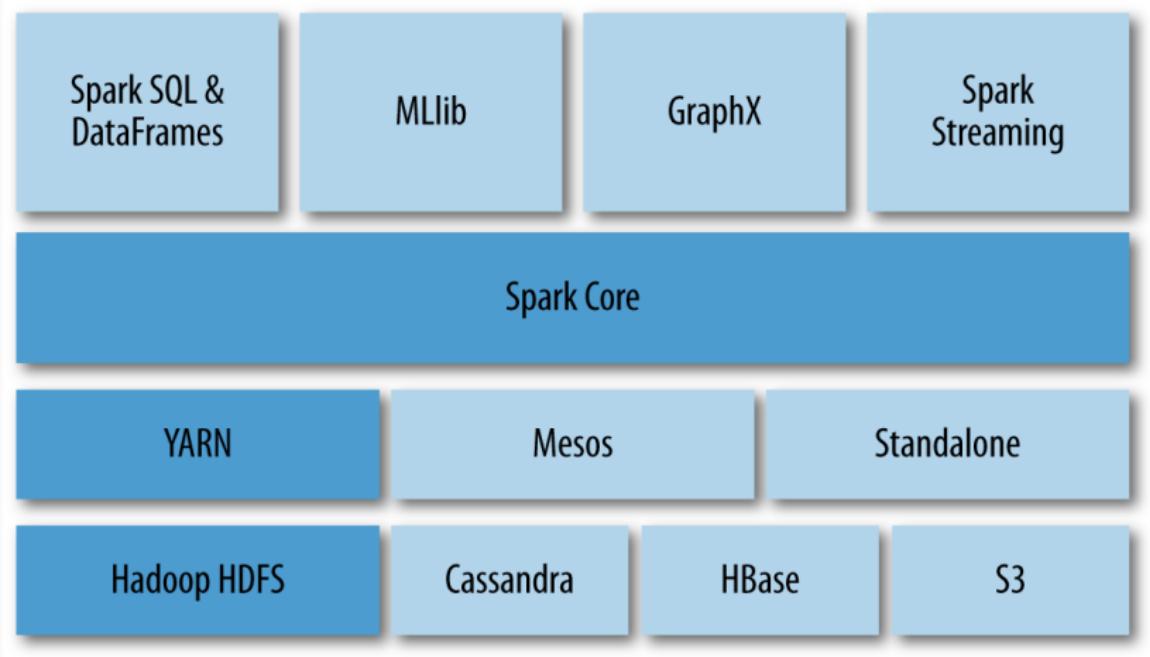

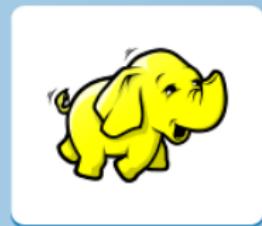

## Comparison to MapReduce

- In-memory data
  - Less i/o overhead
  - Faster operations
  - Caching
- Better for recursive tasks (e.g. machine learning)
- Some libraries are dropping MapReduce support
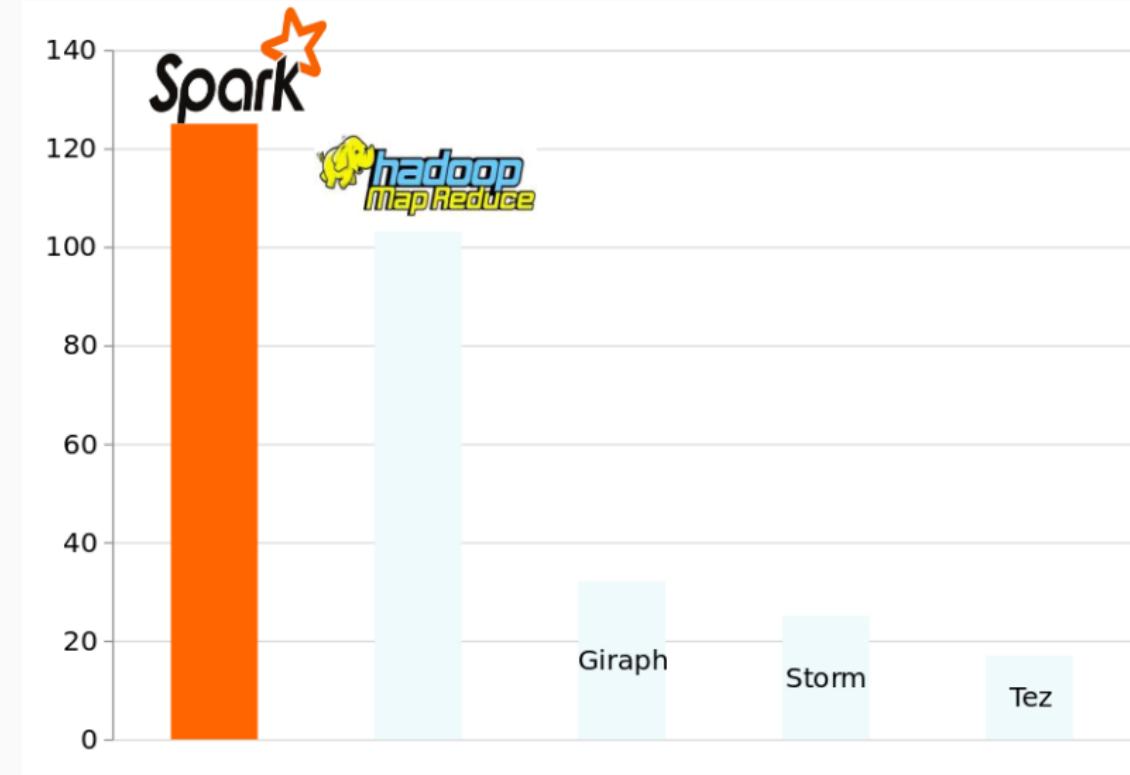

# Project status

## Overview

Data (RDDs/Datasets)

- RDD: Resilient Distributed Dataset
- Collections of objects spread across a cluster, stored in RAM or on Disk
- Built through parallel transformations
- Automatically rebuilt on failure

Operations

- Transformations (e.g. group, map, groupBy)
- Actions (e.g. count, collect, save)
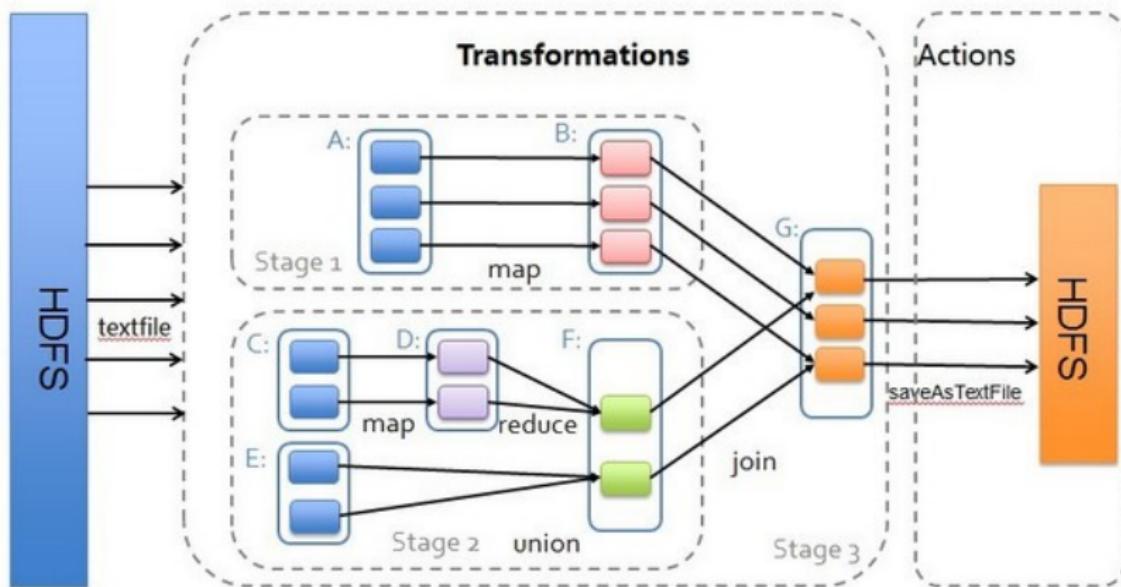

## RDDs vs Datasets

Datasets are the future

- More memory efficient
- Libraries dropping support for RDDs

# RDDs vs Datasets

Distributed Wordcount

| | Execution Time (sec) |
|---|---|
| Datasets | |
| RDDs | |
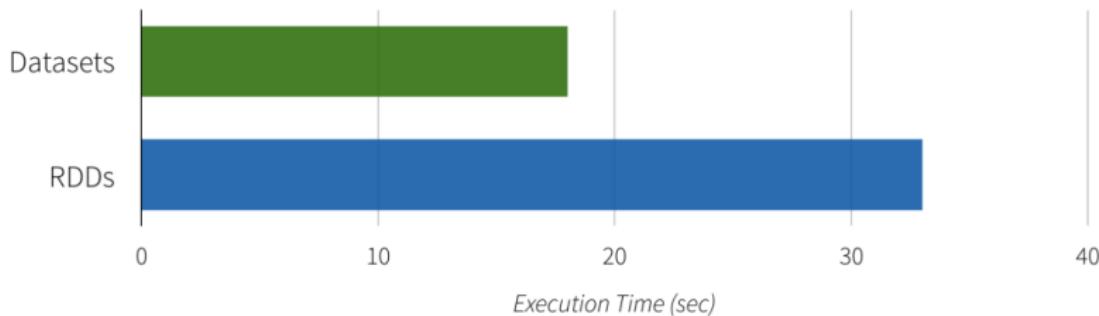

Memory Usage when Caching

| Datasets | |
|---|---|
| RDDs | |
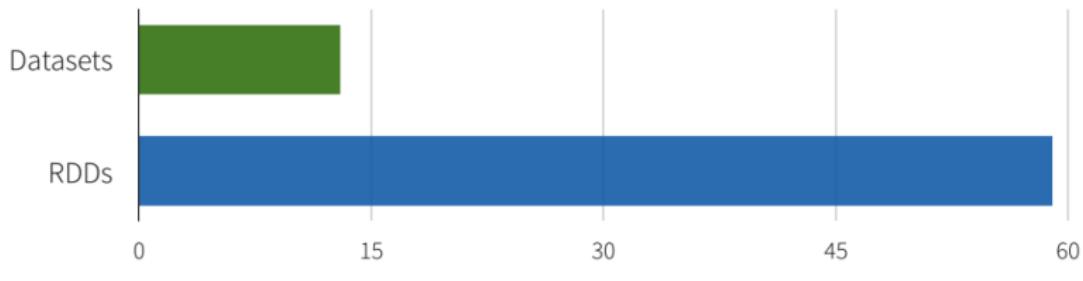

# Language support

Scala

```scala
val lines = sc.textFile(...)
lines.filter(x => x.contains("ERROR")).count()
```

Python

```python
lines = sc.textFile(...)
lines.filter(lambda s: "ERROR" in s).count()
```

Java

```
Removed, to keep the slides clean :)
```

sc is the Spark Context (more or this later)

## Different flavors

| Language | App | REPL | Performance |
|----------|-----|------|-------------|
| Scala    | Yes | Yes  | ☺           |
| Java     | Yes | No   | ☺           |
| Python   | Yes | Yes  | ☺           |

The Read-eval-print-loop (REPL) is the easiest way to get started and explore datasets. It is just a special Spark application that accepts user input (scala code).

# Working with RDDs

# Creation

From normal data structures

```scala
val nums = sc.parallelize(List(1, 2, 3))
val cont = sc.parallelize(List(("a", 1),
                               ("a", 1),
                               ("b", 3)))
```

From distributed/local sources

```scala
sc.textFile('myfile')
```

Note: sc is the spark context in the Spark interpreter

```
collect()
```

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

Runs any pending transformation and returns the real values

```
nums.collect()
> List(1, 2, 3)
cont.collect()
> List((a, 1), (a, 1), (b, 3))
```

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

```
take(N)
```

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

Returns the N first elements

```
nums.take(2)
> List(1, 2)
cont.take(1)
> List((a, 1))
```

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

```
count()
```

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

Returns the number of elements in a collection

```
nums.count()
```

> 3

```
cont.count()
```

> 3

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

```
filter(fn)
```

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

# filter(fn)

This time, we need to define a function.

Filter applies that function to every element, and returns those where the function returns true.

For example:

```
val fn = (x:Int)) => x > 1
```

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

```
val fn = (x:Int)) => x > 1
```

Return a list containing the values where the function returns true

```
nums.filter(fn)
> List(2, 3)
```

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

## Quick aside: anonymous functions and underscores

In scala, we can define "anonymous functions", also known as lambda functions.

## Quick aside: anonymous functions and underscores

In scala, we can define "anonymous functions", also known as lambda functions.

```scala
val fn = (x:Int)) => x > 1
cont.filter(fn)
```

is equivalent to:

```scala
cont.filter((x:Int) => x>1)
```

## Quick aside: anonymous functions and underscores

```scala
val fn = (x:Int)) => x > 1
cont.filter(fn)

cont.filter((x:Int) => x>1)
```

Additionally, the scala compiler is smart enough to infer types in this example. Hence, we could simply write:

```scala
cont.filter(x => x>1)
```

## Quick aside: anonymous functions and underscores

```
val fn = (x:Int)) => x > 1
cont.filter(fn)

cont.filter((x:Int) => x>1)

cont.filter(x => x>1)
```

Furthermore, we could use underscores to replace arguments:

```
cont.filter(_>1)
```

## Quick aside: anonymous functions and underscores

Every new argument in the lambda function represents a parameter

Hence, these two expresions are equivalent

```
_ + _
(x,y) => x+y
```

## Operations: filter

Our last example could be written more concisely as:

```
nums.filter(_>1)
> List(2, 3)
```

What would this filter do?

```
cont.filter(_._1 == "a" && _._1 == 1)
> ???
```

```
<console>:9: error: missing parameter type
for expanded function ((x$1, x$2) =>
x$1._1.$eq$eq(a).$amp$amp(x$2._1.$eq$eq(1)))
Note: The expected type requires a
one-argument function accepting a 2-Tuple.
```

WUT?
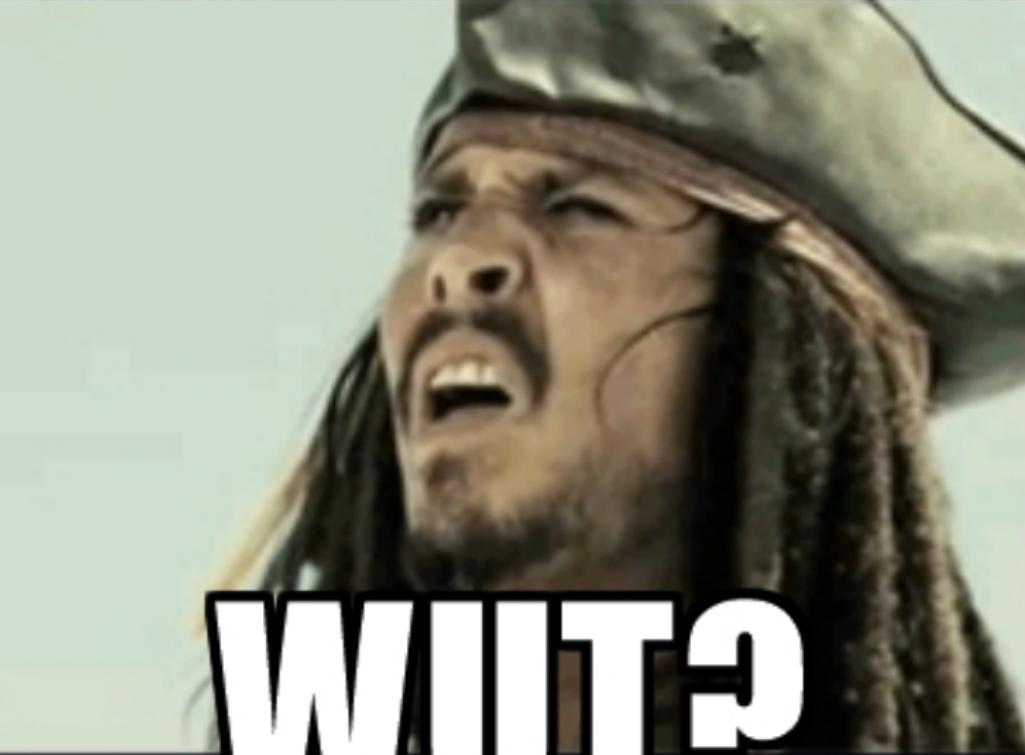

Remember, each new underscore represents a new argument. So that expression expands to:

```
cont.filter((x, y) => x._1 == "a" &&
                 y._2 == 1)
```

The right expression is:

```
cont.filter(x => x._1 == "a" &&
                 x._2 == 1)
> List((a, 1), (a, 1))
```

```
map(fn)
```

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

# Operations: map

Apply a function to every item in the list

```
cont.map(x._2)
> List(1, 1, 3)
nums.map(_*3)
> List(3, 6, 9)
```

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

`reduce(fn)`

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

Merge elements with an associative function (concisely)

```
nums.reduce(_+_)
```

> 6

```
cont.reduce((x, y) => (x._1+y._1,
                       x._2*y._2)
```

> (aab, 3)

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

# groupByKey()

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

Group elements of a list by the first item in the tuple

```
cont.groupByKey()
> [(b, [3]), (a, [1,1])]
```

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

# reduceByKey(fn)

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

[3]Databricks' post on avoiding groupByKey

Group by key and reduce each value

```
cont.reduceByKey((x,y)=>x+y)
> [(b,3), (a,2)]
```

reduceByKey is more efficient than applying group, map and reduce separately. The reduce function can be given to each worker, which avoids passing unnecessary data. [3]

Reminder:

```
nums: List(1, 2, 3)
cont: List(("a", 1), ("a", 1), ("b", 3))
```

---

[3]Databricks' post on avoiding groupByKey

And once you are done, save your results to a file.

```
nums.saveAsTextFile("hdfs://file.txt")
```

# Example: Search in logs

```scala
val lines = sc.textFile("hdfs://...")
val errors = lines.filter(s =>
                        s.startswith("ERROR"))
val messages = errors.map(s => s.split("\t")._2)
messages.cache()
messages.filter(s => s.contains("mysq")).count()
messages.filter(s => s.contains("php").count()
```

# Using Spark

**Local deployment using docker-compose**

Get the repo

```
git clone http://github.com/gettyimages/docker-spark
cd docker-spark
docker-compose up
docker exec -it dockerspark_master_1 bin/spark-shell
```

**Local deployment using docker-compose**

Move to the repo

```
git clone http://github.com/gettyimages/docker-spark
cd docker-spark
docker-compose up
docker exec -it dockerspark_master_1 bin/spark-shell
```

**Local deployment using docker-compose**

Run all the containers

```
git clone http://github.com/gettyimages/docker-spark
cd docker-spark
docker-compose up
docker exec -it dockerspark_master_1 bin/spark-shell
```

**Local deployment using docker-compose**

Launch spark-shell inside the master container

```
git clone http://github.com/gettyimages/docker-spark
cd docker-spark
docker-compose up
docker exec -it dockerspark_master_1 bin/spark-shell
```

  links:
    - master
  volumes:
    - ./conf/worker:/conf
    - ./data:/tmp/data
```

## Useful info

- ./data folder is mounted as /tmp/data
  - Copy your datasets there
  - Load them in the shell: `sc.textFile("/tmp/data/...")`
- Master Web UI (localhost:8080)
- Worker Web UI (localhost:8081)
- REPL Web UI (localhost:4040 when launched)

**A word of caution**: as any other app, the shell reserves resources on startup, whether you are using them or not.

Steps:

- Write the code
- Compile the jar
- Make your data available to every node in the cluster
- Submit it to your cluster

Example application

```scala
import org.apache.spark.SparkContext
import org.apache.spark.SparkContext._
import org.apache.spark.SparkConf

object SparkWordCount {
  def main(args: Array[String]) {
    // create Spark context with Spark configuration
    val sc = new SparkContext(new SparkConf().
        ↳ setAppName("Spark Example"))
  ... Your program ...
}
```

## Running an aplication

```
./bin/spark-submit --class <main-class> \
                   --master <master-url> \
                   --deploy-mode <deploy-mode> \
                   --conf <key>=<value> \
                   ... # other options
                   <application-jar> \
                   [application-arguments]
```

# Full examples

## Word frequency in wikipedia, revisited

Spark

```
val wiki = sc.textFile("Wikipedia.txt")
val counts = wiki.flatMap(line=> line.split(" ")
             map(word => (word, 1)))
             reduceByKey(_ + _)
```

Pure scala

```
val wiki = scala.io.Source.fromFile("Wiki").getLines
wiki.flatMap(line=> line.split(" "))
     map(x=>(x, 1)).toList
     groupBy(x => x._1)
```

Shall we try it in the shell?

## Spark is not magic

- We still have to add more resources
- Caching may cause the spark version to use **more memory** (this can be configured)

- We still have to add more resources
- Caching may cause the spark version to use **more memory** (this can be configured)

# However, it allows us to scale our application

# Page rank

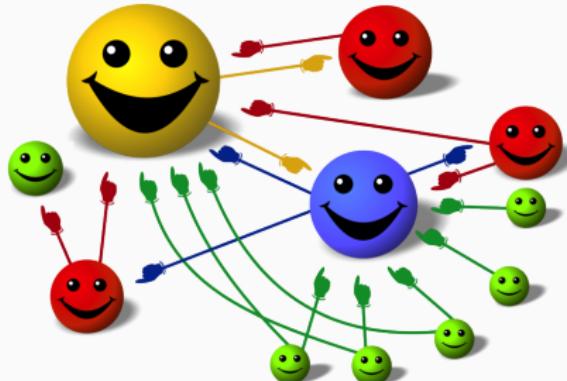

- Created by Google
- Rank given by links and their importance
- Iterative (Perfect for Spark!)

PageRank of site $= \sum \frac{\text{Page rank of inbound link}}{\text{Number of links on that page}}$

OR

$$PR(u) = (1 - d) + d \times \sum \frac{PR(v)}{N(V)}$$

# PageRank toy example

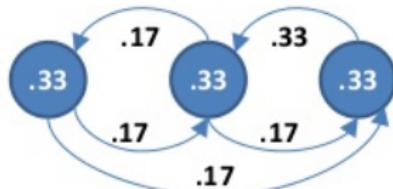

Superstep 0
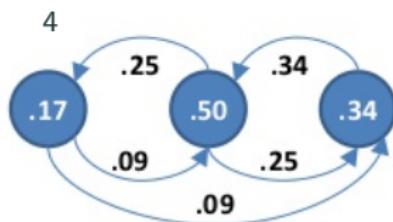

Superstep 1

Superstep 2

**Input graph**
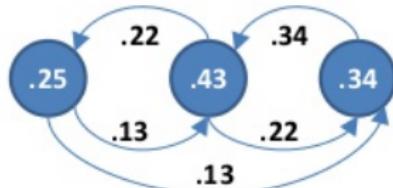

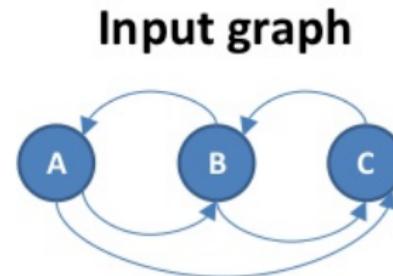

# Spark Program

```scala
val links = // RDD of (url, neighbors) pairs
var ranks = // RDD of (url, rank) pairs

for (i <- 1 to ITERATIONS) {
  val contribs = links.join(ranks).flatMap {
    case (url, (links, rank)) =>
      links.map(dest => (dest, rank/links.size))
  }

}

ranks.saveAsTextFile(...)
```

# Next week

## Next week

- Advanced Spark configuration
- Multiple hosts
- Spark ecosystem
- More examples in IBM BlueMix

# Acknowledgements and useful links

- Spark programming guide
- Databricks introducing apache spark datasets
- Data Analytics with Hadoop: In-Memory Computing with Spark
